1. How LLMs Process Prompts

Before learning prompt techniques, it helps to understand what happens when you send a prompt to an LLM.

The Token Pipeline

When you type "Explain quantum computing", the model doesn't see words — it sees **tokens**. A token is roughly 3-4 characters or about ¾ of a word.

```
Input:  "Explain quantum computing"
Tokens: ["Explain", " quantum", " computing"]    # 3 tokens
```

The model then predicts the **next token** based on all previous tokens, one at a time. Your entire prompt exists to steer this next-token prediction in a useful direction.

Why Prompts Work

LLMs are trained on trillions of tokens from the internet — books, code, conversations, manuals, academic papers. When you write a prompt that looks like a pattern the model has seen before, it "completes" that pattern.

This is why few-shot prompting works: you're showing the model a pattern, and it continues it.

```
# The model has seen millions of examples that look like:
# "Q: [question] A: [answer]"
# So when you write...

Q: What is the capital of France?
```

```
A:

# ...it completes with "Paris" because that pattern is deeply embedded.
```

The Context Window

Every LLM has a maximum number of tokens it can process at once (the **context window**). Everything — your system message, examples, user input, AND the model's response — must fit within this window.

Model	Context Window	Approximate Words
GPT-4o	128K tokens	~96,000 words
GPT-4o-mini	128K tokens	~96,000 words
Claude 3.5 Sonnet	200K tokens	~150,000 words
Gemini 1.5 Pro	2M tokens	~1,500,000 words
Llama 3.1 (8B)	128K tokens	~96,000 words
Mistral Large	128K tokens	~96,000 words

Why this matters for agents: In multi-step agent workflows, each step consumes tokens. If your system message is 2,000 tokens, your few-shot examples are 1,500 tokens, and the user's document is 50,000 tokens — you've already used 53,500 tokens before the model even starts responding.

---

2. Core Prompting Techniques

2.1 Zero-Shot Prompting

Give the model a task with no examples. It relies on its training knowledge.

```
# Zero-shot: Classification
messages = [
    {"role": "user", "content": """Classify this customer feedback as:
positive, negative, or neutral. Output only the label.

Feedback: "The delivery was fast but the packaging was damaged."
Label:"""}
]
```

When to use:

- Simple, well-defined tasks (translation, summarization, basic classification)
- When you want to iterate quickly without crafting examples
- When token budget is tight

When it fails:

- Tasks with custom output formats
- Domain-specific classification with non-obvious categories
- Tasks where the model's default behavior doesn't match your needs

2.2 Few-Shot Prompting

Provide 2-5 input-output examples that demonstrate the pattern.

```
# Few-shot: Named Entity Extraction
messages = [
    {"role": "user", "content": """Extract entities from the text.

Text: "Tim Cook announced the new iPhone at Apple Park in Cupertino."
Entities: {"person": ["Tim Cook"], "product": ["iPhone"], "location": ["Apple Park",
"Cupertino"], "org": ["Apple"]}

Text: "Sundar Pichai revealed Gemini 2.0 at Google I/O in Mountain View."
Entities: {"person": ["Sundar Pichai"], "product": ["Gemini 2.0"], "location":
["Mountain View"], "org": ["Google"]}

Text: "Jensen Huang showcased the Blackwell GPU at NVIDIA's GTC conference in San
Jose."
Entities:"""}
]
```

Best practices for few-shot:

Practice	Why
Use 3-5 examples	Fewer may not establish the pattern; more wastes tokens
Cover edge cases	Include at least one tricky example
Keep format identical	The model mimics your exact formatting
Vary the content	Don't use similar inputs — show diversity
Order matters	Place simpler examples first, harder ones last
Balance labels	Don't show 4 "positive" and 1 "negative"

2.3 One-Shot Prompting

A single example. Useful when you just need to demonstrate the output format.

```
messages = [
    {"role": "user", "content": """Convert the meeting notes to action items.

Notes: "We discussed the Q3 budget. Maria will finalize the spreadsheet by Friday.
John needs to review the vendor contracts."
Action Items:
- [ ] Maria: Finalize Q3 budget spreadsheet (Due: Friday)
- [ ] John: Review vendor contracts (Due: TBD)

Notes: "Sprint retrospective. Team agreed to switch to daily standups.
Sarah will set up the new Jira board. We need to migrate tickets by Monday."
```

```
Action Items:"""}
]
```

---

3. Advanced Prompting Techniques

3.1 Chain-of-Thought (CoT)

Force the model to reason step by step before answering. Dramatically improves performance on math, logic, and multi-step reasoning.

```
# WITHOUT Chain-of-Thought
messages = [
    {"role": "user", "content": "If a shirt costs $25 and is on 20% sale, and you
have a $5 coupon, how much do you pay?"}
]
# Model might jump to an answer and get it wrong

# WITH Chain-of-Thought
messages = [
    {"role": "user", "content": """If a shirt costs $25 and is on 20% sale, and you
have a $5 coupon,
how much do you pay?

Think step by step:"""}
]
# Model will reason through:
# Step 1: Original price = $25
# Step 2: 20% discount = $25 × 0.20 = $5
# Step 3: Price after discount = $25 - $5 = $20
# Step 4: Apply $5 coupon = $20 - $5 = $15
# Answer: $15
```

Few-shot CoT — even more powerful:

```
messages = [
    {"role": "user", "content": """Solve these problems step by step.

Q: A store has 45 apples. They sell 12 in the morning and receive a shipment of 30
in the afternoon. How many do they have?
Reasoning: Start with 45. Sell 12: 45-12=33. Receive 30: 33+30=63.
Answer: 63

Q: A car travels 60 km/h for 2.5 hours, then 80 km/h for 1.5 hours. Total distance?
Reasoning: First leg: 60×2.5=150 km. Second leg: 80×1.5=120 km. Total: 150+120=270
km.
Answer: 270 km

Q: A recipe serves 4 people and needs 2.5 cups of flour. How much flour for 10
people?
```

```
Reasoning:"""}
]
```

3.2 ReAct (Reason + Act)

The model alternates between **thinking** (reasoning) and **acting** (calling tools). This is the foundation of most modern AI agents.

```
system_message = """You are a research assistant with access to tools.

For each user query, follow this pattern:
Thought: [reason about what you need to do]
Action: [tool_name(parameters)]
Observation: [result from the tool]
... (repeat as needed)
Thought: [final reasoning]
Answer: [final response to the user]

Available tools:
- search(query): Search the web
- calculate(expression): Evaluate a math expression
- lookup_db(sql): Query the product database
"""

user_message = "What's the current price of AAPL stock, and how much would 50 shares
cost?"

# The model would generate:
# Thought: I need to find the current AAPL stock price first.
# Action: search("AAPL stock price today")
# Observation: AAPL is trading at $198.50
# Thought: Now I need to calculate the cost of 50 shares.
# Action: calculate("50 * 198.50")
# Observation: 9925.0
# Thought: I have all the information needed.
# Answer: AAPL is currently trading at $198.50. Purchasing 50 shares would cost
$9,925.00.
```

Why ReAct matters for agents: This is the pattern used by LangChain agents, AutoGen, and CrewAI. When you build agents in Sessions 15-18, every agent loop uses a variant of ReAct.

3.3 Tree-of-Thought (ToT)

Instead of a single reasoning chain, the model explores **multiple paths** and evaluates which is most promising. Used for complex problems with multiple valid approaches.

```
messages = [
    {"role": "system", "content": """When solving complex problems, explore multiple
approaches:

Approach 1: [describe first strategy]
```

```
Evaluation: [strengths and weaknesses]

Approach 2: [describe second strategy]
Evaluation: [strengths and weaknesses]

Approach 3: [describe third strategy]
Evaluation: [strengths and weaknesses]

Best approach: [select and justify]
Solution: [implement the best approach]"""},

    {"role": "user", "content": "Design a caching strategy for an API that serves
10,000 requests/second with data that changes every 5 minutes."}
]
```

3.4 Self-Consistency

Run the same prompt multiple times and take the majority answer. Simple but effective for factual and reasoning tasks.

```python
import collections

def self_consistent_answer(prompt, n_samples=5, temperature=0.7):
    """Run the prompt multiple times and return the majority answer."""
    answers = []
    for _ in range(n_samples):
        response = client.chat.completions.create(
            model="gpt-4o-mini",
            messages=[{"role": "user", "content": prompt}],
            temperature=temperature,
        )
        answers.append(response.choices[0].message.content.strip())

    # Return the most common answer
    counter = collections.Counter(answers)
    majority_answer, count = counter.most_common(1)[0]
    confidence = count / n_samples

    return majority_answer, confidence, counter

answer, conf, distribution = self_consistent_answer(
    "What is 17 * 23? Answer with just the number.",
    n_samples=5
)
print(f"Answer: {answer} (confidence: {conf:.0%})")
print(f"Distribution: {distribution}")
```

3.5 Reflexion (Self-Reflection)

The model critiques its own output and improves it. This is a key pattern in agentic AI — agents that can self-correct.

```
# Step 1: Generate initial response
messages = [
    {"role": "user", "content": "Write a Python function to check if a string is a
valid email address."}
]
initial_response = call_llm(messages)

# Step 2: Self-critique
messages = [
    {"role": "user", "content": f"""Review this code for bugs, edge cases, and
improvements.

Code:
{initial_response}

List every issue you find, then provide a corrected version.
Be harsh — assume there are problems."""}
]
critique = call_llm(messages)

# Step 3: Final refinement
messages = [
    {"role": "user", "content": f"""Given this original code and critique, produce
the final version.

Original:
{initial_response}

Critique:
{critique}

Write the final, production-ready version:"""}
]
final_code = call_llm(messages)
```

3.6 Decomposition (Least-to-Most Prompting)

Break complex problems into sub-problems, solve each one, then combine.

```
messages = [
    {"role": "system", "content": """When given a complex task, first decompose it
into sub-tasks.
Solve each sub-task in order, using the results of previous sub-tasks.
Finally, combine all results into a complete answer."""},

    {"role": "user", "content": """Build a recommendation for whether our company
should migrate
from on-premise servers to AWS cloud.

Consider: cost, security, scalability, team expertise, and migration risk."""}
]
```

```
# The model will decompose into:
# Sub-task 1: Analyze current on-premise costs
# Sub-task 2: Estimate AWS costs for equivalent workload
# Sub-task 3: Compare security posture
# Sub-task 4: Assess scalability requirements
# Sub-task 5: Evaluate team's cloud expertise
# Sub-task 6: Identify migration risks
# Final: Synthesize recommendation from all sub-tasks
```

3.7 Role Prompting (Persona Prompting)

Assign the model a specific expert role. This activates domain-specific knowledge and communication patterns.

```
# Generic prompt → generic answer
messages = [
    {"role": "user", "content": "How should I structure my investment portfolio?"}
]

# Role prompt → expert-level answer
messages = [
    {"role": "system", "content": """You are a Chartered Financial Analyst (CFA)
with 20 years
of experience managing portfolios for high-net-worth individuals. You specialize in
risk-adjusted returns and modern portfolio theory. You always consider the client's
risk tolerance, time horizon, and tax situation before making recommendations.
You cite specific allocation percentages and explain the rationale behind each
choice."""},
    {"role": "user", "content": "How should I structure my investment portfolio?"}
]
```

Tip: The more specific the role, the better. "You are a doctor" is weak. "You are a board-certified cardiologist at a teaching hospital who explains conditions to patients in simple terms" is strong.

3.8 Generated Knowledge Prompting

Ask the model to generate relevant knowledge first, then use that knowledge to answer.

```
# Step 1: Generate knowledge
messages = [
    {"role": "user", "content": """Generate 5 key facts about how photovoltaic cells
convert
sunlight into electricity. Be specific and technical."""}
]
knowledge = call_llm(messages)

# Step 2: Use the knowledge to answer a specific question
messages = [
    {"role": "user", "content": f"""Using the following knowledge:
```

```
{knowledge}

Explain to a 10-year-old how solar panels work. Use analogies they'd understand."""}
]
```

---

4. LLM Prompting vs Agentic Prompting

This is a critical distinction for this course. Traditional LLM prompting and agentic prompting serve fundamentally different purposes.

4.1 The Core Difference

Dimension	LLM Prompting	Agentic Prompting
Goal	Get a single good response	Orchestrate multi-step workflows
Who reads the output	A human	Both code AND other LLM calls
Output format	Flexible (human-readable)	Strict (machine-parseable)
Error handling	Human retries manually	Agent must self-correct
State	Stateless (one-shot)	Stateful (conversation history, memory)
Tools	None	Web search, APIs, databases, code execution
Autonomy	None — human in the loop	Semi to fully autonomous
Prompt complexity	Simple to moderate	Highly structured with multiple sections

4.2 LLM Prompting — "One-Shot Conversation"

Traditional LLM prompting is what most people think of: you write a prompt, get a response, done.

```
# Traditional LLM prompting — human reads the output
response = client.chat.completions.create(
    model="gpt-4o",
    messages=[
        {"role": "system", "content": "You are a helpful writing assistant."},
        {"role": "user", "content": "Write a professional email declining a meeting
invitation."}
    ],
    temperature=0.7,
)
print(response.choices[0].message.content)
# Human reads this, maybe edits it, sends it
```

4.3 Agentic Prompting — "Autonomous Workflow"

Agentic prompting designs prompts where the output is consumed by **code** or **other agents**. The output must be structured, predictable, and machine-parseable.

```
# Agentic prompting — code parses the output
import json

# Step 1: Router Agent — classifies the user's intent
router_system = """You are a task router. Classify the user's request into exactly
one category.

Categories:
- "search": User wants to find information
- "calculate": User wants a math computation
- "create": User wants to generate content
- "analyze": User wants to analyze data

Respond with ONLY a JSON object: {"category": "<category>", "confidence": <0-1>}
No other text."""

response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[
        {"role": "system", "content": router_system},
        {"role": "user", "content": "What were Apple's earnings last quarter?"}
    ],
    temperature=0.0,  # Deterministic for routing
)

# Code parses the output — this MUST be valid JSON
result = json.loads(response.choices[0].message.content)
print(result)  # {"category": "search", "confidence": 0.95}

# Step 2: Route to the appropriate specialist agent
if result["category"] == "search":
    # Hand off to search agent with its own specialized system message
    search_system = """You are a financial research agent.
    Given a search query, generate 3 specific search queries to find the answer.
    Respond as JSON: {"queries": ["query1", "query2", "query3"]}"""
    # ... continue the pipeline
```

4.4 Key Principles of Agentic Prompting

Principle 1: Structured Output is Non-Negotiable

In agentic workflows, the output of one step is the input to the next. If the LLM returns free-form text when your code expects JSON, the pipeline breaks.

```
# BAD: Free-form output that code can't parse
system = "Analyze the sentiment of user messages."
# Output: "The message seems to be expressing frustration, possibly negative..."
```

```
# GOOD: Structured output that code can reliably parse
system = """Analyze sentiment. Respond ONLY with this exact JSON format:
{"sentiment": "positive|negative|neutral|mixed", "confidence": 0.0-1.0,
"key_phrases": ["phrase1", "phrase2"]}
No markdown. No explanation. Just the JSON."""
# Output: {"sentiment": "negative", "confidence": 0.85, "key_phrases":
["frustrated", "broken again"]}
```

Principle 2: Explicit Tool Descriptions

Agents need to know what tools they have and exactly how to call them.

```
tool_prompt = """You have access to these tools:

1. search_web(query: str) → str
   Search the internet. Returns top 3 results as text.
   Example: search_web("Python 3.12 release date")

2. run_python(code: str) → str
   Execute Python code in a sandbox. Returns stdout.
   Example: run_python("print(sum(range(100)))")

3. query_database(sql: str) → str
   Run a read-only SQL query against the company database.
   Tables: users(id, name, email, created_at), orders(id, user_id, amount, date)
   Example: query_database("SELECT COUNT(*) FROM users WHERE created_at > '2024-01-
01'")

To use a tool, respond with:
TOOL: tool_name
INPUT: the input value

After receiving the tool result, continue reasoning."""
```

Principle 3: Error Recovery Instructions

Agents must know what to do when things go wrong.

```
system = """You are a data extraction agent.

## Error Handling
- If the input document is empty or unreadable, respond: {"error":
"UNREADABLE_INPUT", "message": "..."}
- If you cannot extract a required field, set it to null — NEVER make up values
- If the extracted data seems inconsistent (e.g., end_date before start_date), flag
it:
  {"warning": "INCONSISTENT_DATES", "extracted": {...}, "issue": "..."}
- If you need clarification from the user, respond: {"status":
"NEEDS_CLARIFICATION", "question": "..."}
"""
```

Principle 4: Single Responsibility Per Agent

Each agent prompt should do ONE thing well. Don't overload a single prompt.

```
# BAD: One prompt tries to do everything
system = """You are an AI assistant. Help users with research, writing,
code generation, data analysis, scheduling, and customer support."""
# This agent will be mediocre at everything

# GOOD: Specialized agents with focused prompts
research_agent_system = """You are a research specialist. Your ONLY job is to
take a research question and produce a structured research brief with:
- 3-5 key findings
- Sources for each finding
- Confidence level (high/medium/low)
- Gaps in available information
Respond in JSON format."""

writing_agent_system = """You are a technical writer. Your ONLY job is to
take a research brief (JSON) and produce a well-structured document.
You never conduct research — you only write from provided facts."""
```

Principle 5: State Management in Prompts

Agents need to track what they've done and what's left to do.

```
system = """You are a task execution agent. You will receive:
1. A goal to accomplish
2. A list of completed steps (may be empty)
3. Available tools

Based on the completed steps, determine the NEXT single step to take.
Do NOT try to do everything at once. One step at a time.

Respond with:
{"next_action": "tool_name", "input": "...", "reasoning": "why this step is next"}

If the goal is fully achieved, respond:
{"status": "complete", "summary": "what was accomplished"}
"""

# Each iteration, you update the completed_steps list:
user_message = f"""Goal: Find and summarize the top 3 AI papers from last week

Completed steps:
1. Searched "top AI papers March 2025" → found arxiv links
2. Fetched paper #1: "Attention is All You Still Need" → summarized

Available tools: search_web, fetch_url, summarize_text

What is the next step?"""
```

4.5 Side-by-Side Comparison

Here's the same task — analyzing customer reviews — done with LLM prompting vs agentic prompting:

LLM Approach (human-readable output):

```
messages = [
    {"role": "user", "content": """Analyze these customer reviews and give me
insights:

1. "Love the product but shipping took forever"
2. "Terrible quality, returning immediately"
3. "Best purchase I've made this year!"
4. "It's okay, does the job but nothing special"
5. "Customer service was unhelpful when I had issues"
"""}
]
# Output: A paragraph of human-readable analysis
```

Agentic Approach (machine-parseable, multi-step):

```
# Step 1: Classification Agent
classification_system = """Classify each review. Respond as JSON array:
[{"id": 1, "text": "...", "sentiment": "positive|negative|neutral|mixed",
  "topics": ["topic1", "topic2"], "urgency": "high|medium|low"}]"""

# Step 2: Aggregation Agent (receives Step 1's JSON output)
aggregation_system = """Given classified review data (JSON), produce summary
statistics.
Respond as JSON:
{"total": N, "sentiment_distribution": {"positive": N, ...},
 "top_topics": [{"topic": "...", "count": N, "avg_sentiment": "..."}],
 "urgent_issues": [{"id": N, "text": "...", "reason": "..."}]}"""

# Step 3: Action Agent (receives Step 2's JSON output)
action_system = """Given review analytics (JSON), generate specific action items.
Respond as JSON:
{"actions": [{"priority": "high|medium|low", "department": "...",
  "action": "...", "expected_impact": "..."}]}"""

# Each step feeds into the next, fully automated
```

---

5. Sampling Parameters Deep Dive

5.1 Temperature

The most important parameter. Controls randomness in token selection.

```
# The softmax function with temperature:
# p(token_i) = exp(logit_i / T) / Σ exp(logit_j / T)
```

```
#
# T → 0: Becomes argmax (greedy, deterministic)
# T = 1: Standard softmax (model's natural distribution)
# T → ∞: Uniform distribution (random)

# Practical demonstration
prompt = "The capital of France is"

# Temperature 0.0 — always returns "Paris"
# Temperature 0.5 — almost always "Paris", occasionally "Paris," or "Paris."
# Temperature 1.0 — usually "Paris", sometimes starts a longer response
# Temperature 2.0 — might say "Lyon" or something unexpected

responses_by_temp = {}
for temp in [0.0, 0.5, 1.0, 1.5]:
    responses = []
    for _ in range(5):
        r = client.chat.completions.create(
            model="gpt-4o-mini",
            messages=[{"role": "user", "content": prompt}],
            temperature=temp,
            max_tokens=10,
        )
        responses.append(r.choices[0].message.content.strip())
    responses_by_temp[temp] = responses
    print(f"Temp {temp}: {responses}")
```

Temperature Guidelines for Agentic AI:

Agent Step	Temperature	Why
Router / Classifier	0.0	Must be deterministic
Tool selection	0.0	Wrong tool = broken pipeline
Data extraction	0.0–0.2	Accuracy over creativity
Summarization	0.3–0.5	Some flexibility in wording
Conversation / Chat	0.5–0.7	Natural, varied responses
Creative generation	0.7–1.0	Diverse, interesting output
Brainstorming	0.9–1.2	Maximum diversity

5.2 top_p (Nucleus Sampling)

Instead of a hard cutoff on number of tokens, top_p dynamically selects the smallest set of tokens whose cumulative probability exceeds p.

```
Example: Model predicts next token after "The cat sat on the"

Token probabilities:
```

```
  "mat"     → 0.40
  "floor"   → 0.25
  "couch"   → 0.15
  "table"   → 0.08
  "roof"    → 0.05
  "moon"    → 0.03
  "dragon"  → 0.02
  ... (long tail)

top_p = 0.5:  Only considers {"mat", "floor"} (0.40 + 0.25 = 0.65 ≥ 0.5)
top_p = 0.8:  Considers {"mat", "floor", "couch"} (0.40 + 0.25 + 0.15 = 0.80)
top_p = 0.95: Considers {"mat", "floor", "couch", "table", "roof"}
top_p = 1.0:  Considers all tokens (default)
```

```python
response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[{"role": "user", "content": "Write a poem about rain."}],
    temperature=1.0,  # Use one or the other
    top_p=0.9,        # Not recommended to set both — see below
)
```

The Golden Rule: Adjust temperature OR top_p, not both. They both control randomness through different mechanisms, and combining them creates unpredictable interactions.

5.3 top_k

A simpler approach: only consider the top K most probable tokens.

```
top_k = 1:   Only "mat" → greedy decoding
top_k = 3:   {"mat", "floor", "couch"} → sample among these
top_k = 50:  Top 50 tokens → common default
top_k = 0:   Consider all tokens (disabled)
```

API support:

API	temperature	top_p	top_k	frequency_penalty	presence_penalty
OpenAI	✅	✅	❌	✅	✅
Anthropic (Claude)	✅	✅	✅	❌	❌
Google (Gemini)	✅	✅	✅	✅	✅
HuggingFace	✅	✅	✅	✅	✅
Ollama (local)	✅	✅	✅	✅	✅

5.4 Frequency & Presence Penalties

Both fight repetition, but differently:

```
# FREQUENCY PENALTY: Proportional to occurrence count
# Token "the" appeared 15 times → gets a BIG penalty
# Token "however" appeared 2 times → gets a SMALL penalty
# Effect: Reduces word repetition proportionally

response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[{"role": "user", "content": "Write a 200-word product description for
headphones."}],
    frequency_penalty=0.0,  # Default: no penalty
)

# vs

response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[{"role": "user", "content": "Write a 200-word product description for
headphones."}],
    frequency_penalty=1.5,  # Strong anti-repetition
)

# PRESENCE PENALTY: Flat penalty for ANY token that appeared at all
# Token "the" appeared 15 times → gets the SAME penalty as
# Token "however" appeared 1 time → same flat penalty
# Effect: Encourages introducing new topics/words

response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[{"role": "user", "content": "Write a 200-word product description for
headphones."}],
    presence_penalty=1.0,  # Encourages topic diversity
)
```

For agents: If your agent is stuck in a repetitive loop (common with poorly designed agent loops), increase `frequency_penalty` to 0.5–1.0.

5.5 max_tokens

Controls the maximum length of the model's response. Critical for cost control and pipeline predictability.

```
# For a classification agent — you only need a few tokens
response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[...],
    max_tokens=20,  # "positive", "negative", etc. — don't need 1000 tokens
)

# For a summarization agent — allow more space
response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[...],
```

```
    max_tokens=500,
)
```

Warning: If `max_tokens` is too low, the response gets cut off mid-sentence. For JSON output, a truncated response = invalid JSON = broken pipeline.

5.6 stop Sequences

Tell the model to stop generating when it hits a specific string. Extremely useful for structured output.

```
# Stop after the model generates the answer
response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[{"role": "user", "content": "Q: What is 2+2?\nA:"}],
    stop=["\n", "Q:"],  # Stop at newline or next question
)
# Output: " 4" (and nothing else)
```

---

6. System Message Engineering

6.1 The Four Pillars

Every effective system message has four components:

```
system_message = """
# 1. ROLE / PERSONA
You are [specific role] with [experience/expertise]. You communicate in
[style/tone].

# 2. BEHAVIORAL RULES
## Must Do:
- [Rule 1]
- [Rule 2]
- [Rule 3]

## Must Not:
- [Constraint 1]
- [Constraint 2]

## Priority Handling:
- If [ambiguous situation], then [specific action]

# 3. OUTPUT FORMAT
Respond in this exact format:
{
  "field1": "description",
  "field2": "description"
}

# 4. CONTEXT / KNOWLEDGE
```

```
Background information:
- [Domain knowledge 1]
- [Domain knowledge 2]
- [User preferences or constraints]
"""
```

6.2 Complete Example: Customer Support Agent

```
customer_support_system = """You are Alex, a senior customer support specialist at
TechGadgets Inc.,
an online electronics retailer. You have 8 years of experience and are known for
being patient,
empathetic, and solution-oriented. You use a warm but professional tone.

## Rules
### Must Do:
- Always greet the customer by name if provided
- Acknowledge the customer's frustration before jumping to solutions
- Provide specific next steps, not vague promises
- Include order numbers, tracking links, or reference IDs when available
- Escalate to a human agent if the issue involves: refunds over $500, legal threats,
  or safety concerns

### Must Not:
- Never admit fault on behalf of the company without checking policy
- Never share internal processes or system details
- Never make promises about timelines you can't guarantee
- Never be dismissive of the customer's experience

### Priority:
- If the customer is angry, prioritize empathy over efficiency
- If the customer asks for something outside your capability, explain what you CAN
do

## Output Format
Start every response with a brief empathetic acknowledgment (1 sentence).
Then provide the solution or next steps.
End with a clear call-to-action.

If you need to look up information, say: [LOOKUP_NEEDED: order_id/topic]

## Context
- Returns are accepted within 30 days with receipt
- Shipping takes 3-7 business days (standard) or 1-2 days (express)
- Current known issue: Batch #4521 of wireless earbuds has a Bluetooth connectivity
bug
- Warranty: 1 year for electronics, 6 months for accessories
"""
```

6.3 System Message Anti-Patterns

```
# ❌ TOO VAGUE
"You are a helpful assistant."
# Problem: Changes almost nothing about model behavior

# ❌ CONTRADICTORY
"Be concise and brief. Always provide comprehensive, detailed explanations."
# Problem: Model doesn't know which instruction to follow

# ❌ NO FORMAT SPEC
"Analyze the data and give me insights."
# Problem: In an agentic pipeline, the next step can't parse free text

# ❌ OVERLOADED (2000+ words)
"[entire company handbook pasted here]"
# Problem: Key instructions get lost in the noise. Keep it focused.

# ❌ NEGATIVE-ONLY
"Don't be rude. Don't make things up. Don't be verbose. Don't use jargon."
# Problem: Tells the model what NOT to do but not what TO do
```

---

7. Prompt Templates & Variable Injection

In real agent systems, prompts aren't static strings — they're templates with variables.

7.1 Python f-strings (Simple)

```python
def classify_ticket(ticket_text, categories):
    """Classify a support ticket into predefined categories."""
    category_list = ", ".join(categories)

    messages = [
        {"role": "system", "content": f"""You are a support ticket classifier.
Classify the ticket into exactly one category: {category_list}.
Respond with ONLY the category name."""},
        {"role": "user", "content": ticket_text}
    ]

    response = client.chat.completions.create(
        model="gpt-4o-mini",
        messages=messages,
        temperature=0.0,
    )
    return response.choices[0].message.content.strip()

# Usage
result = classify_ticket(
    "My payment was charged twice",
    ["billing", "technical", "shipping", "account", "general"]
)
```

7.2 LangChain PromptTemplate

```
from langchain_core.prompts import ChatPromptTemplate, SystemMessagePromptTemplate,
HumanMessagePromptTemplate

# Define a reusable template
analysis_prompt = ChatPromptTemplate.from_messages([
    SystemMessagePromptTemplate.from_template(
        """You are a {domain} expert analyst.
Analyze the provided data and produce a report.
Focus on: {focus_areas}.
Respond in {output_format} format."""
    ),
    HumanMessagePromptTemplate.from_template(
        "Analyze this data:\n{data}"
    ),
])

# Use the template with different variables
messages = analysis_prompt.format_messages(
    domain="financial",
    focus_areas="revenue trends, risk factors, growth opportunities",
    output_format="JSON",
    data="Q1 Revenue: $2.3M, Q2 Revenue: $2.1M, Q3 Revenue: $2.8M, Q4 Revenue:
$3.1M"
)
```

7.3 Jinja2 Templates (Complex Agents)

For agents with conditional logic in prompts:

```
from jinja2 import Template

agent_template = Template("""You are a {{ agent_role }} agent.

{% if tools %}
## Available Tools
{% for tool in tools %}
- {{ tool.name }}({{ tool.params }}): {{ tool.description }}
{% endfor %}
{% endif %}

{% if memory %}
## Previous Interactions
{% for entry in memory[-5:] %}
- User: {{ entry.user_msg }}
  Agent: {{ entry.agent_msg | truncate(100) }}
{% endfor %}
{% endif %}
```

```
## Current Task
{{ task_description }}

{% if constraints %}
## Constraints
{% for c in constraints %}
- {{ c }}
{% endfor %}
{% endif %}
""")

# Render with dynamic context
prompt = agent_template.render(
    agent_role="research",
    tools=[
        {"name": "search", "params": "query: str", "description": "Search the web"},
        {"name": "summarize", "params": "text: str", "description": "Summarize a
document"},
    ],
    memory=[
        {"user_msg": "Find info on quantum computing", "agent_msg": "I found several
papers..."},
    ],
    task_description="Find the latest breakthroughs in quantum error correction",
    constraints=["Only use peer-reviewed sources", "Focus on results from 2024-
2025"],
)
```

---

8. Output Parsing & Structured Responses

8.1 JSON Mode (OpenAI)

```
response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[
        {"role": "system", "content": "Extract entities from text. Respond as JSON
with keys: persons, organizations, locations."},
        {"role": "user", "content": "Elon Musk visited the Tesla factory in Austin,
Texas."}
    ],
    response_format={"type": "json_object"},  # Forces valid JSON output
)
entity_data = json.loads(response.choices[0].message.content)
```

8.2 Structured Outputs with Pydantic

```
from pydantic import BaseModel
from typing import Literal
```

```python
class SentimentResult(BaseModel):
    sentiment: Literal["positive", "negative", "neutral", "mixed"]
    confidence: float
    key_phrases: list[str]
    summary: str

# Use with OpenAI's structured output
response = client.beta.chat.completions.parse(
    model="gpt-4o-mini",
    messages=[
        {"role": "system", "content": "Analyze the sentiment of the review."},
        {"role": "user", "content": "Great product but terrible packaging. It
arrived damaged."}
    ],
    response_format=SentimentResult,
)
result = response.choices[0].message.parsed
print(result.sentiment)      # "mixed"
print(result.confidence)     # 0.85
print(result.key_phrases)    # ["great product", "terrible packaging", "arrived
damaged"]
```

8.3 Fallback Parsing (When JSON Mode Isn't Available)

```python
import json
import re

def robust_json_parse(text):
    """Parse JSON from LLM output, handling common issues."""
    # Try direct parse first
    try:
        return json.loads(text)
    except json.JSONDecodeError:
        pass

    # Try extracting JSON from markdown code blocks
    json_match = re.search(r'```(?:json)?\s*\n?(.*?)\n?```', text, re.DOTALL)
    if json_match:
        try:
            return json.loads(json_match.group(1))
        except json.JSONDecodeError:
            pass

    # Try finding JSON object in the text
    json_match = re.search(r'\{.*\}', text, re.DOTALL)
    if json_match:
        try:
            return json.loads(json_match.group())
        except json.JSONDecodeError:
            pass
```

```
    raise ValueError(f"Could not parse JSON from: {text[:200]}...")
```

---

9. Common Failure Modes & Fixes

9.1 Failure Mode Catalog

Problem	Cause	Fix
Model ignores instructions	System message too long or vague	Shorten, use markdown headers, put critical rules first
Output format inconsistent	No examples or unclear format spec	Add few-shot examples with exact format
Model hallucinates facts	No grounding data provided	Use RAG (covered in Session 10-12) or add factual context
Model is too verbose	No length constraint	Add "Respond in 2-3 sentences" or set max_tokens
Model refuses safe requests	Overly cautious system message	Relax constraints, be specific about what IS allowed
JSON output is invalid	No JSON mode, too creative temp	Use response_format: json_object, temperature 0
Agent loops infinitely	No exit condition in prompt	Add "If the goal is achieved, respond with DONE"
Wrong tool selection	Tool descriptions too similar	Make tool descriptions more distinct, add examples
Inconsistent between runs	Temperature too high	Lower temperature for deterministic steps
Output in wrong language	No language specification	Explicitly state "Respond in English"

9.2 The Prompt Debugging Checklist

When a prompt isn't working, check these in order:

```
1. □ Is the instruction clear to a human? (If you can't follow it, the model can't
either)
2. □ Is the output format explicitly specified?
3. □ Are there examples? (If not, add 2-3)
4. □ Is the temperature appropriate for the task?
5. □ Is the system message focused? (Under 500 words ideally)
6. □ Are contradictory instructions present?
7. □ Is important context missing?
8. □ Is the model the right one for this task? (gpt-4o-mini may fail where gpt-4o
succeeds)
```

```
9. □ Are you hitting the context window limit?
10. □ Have you tested with adversarial inputs?
```

---

10. Prompting Across Different LLMs

Different models have different strengths and quirks. Here's what to know:

10.1 OpenAI (GPT-4o, GPT-4o-mini)

```python
# OpenAI uses the standard messages format
# Supports: system, user, assistant roles
# Special features: JSON mode, structured outputs, function calling

from openai import OpenAI
client = OpenAI()

response = client.chat.completions.create(
    model="gpt-4o-mini",
    messages=[
        {"role": "system", "content": "You are a helpful assistant."},
        {"role": "user", "content": "Hello!"}
    ],
    temperature=0.7,
    max_tokens=500,
    response_format={"type": "json_object"},  # OpenAI-specific
)
```

10.2 Anthropic (Claude)

```python
# Claude uses a separate system parameter (not in messages array)
# Tends to be more cautious/verbose by default
# Excels at: Long documents, careful analysis, following complex instructions

from anthropic import Anthropic
client = Anthropic()

response = client.messages.create(
    model="claude-sonnet-4-20250514",
    max_tokens=1024,
    system="You are a helpful assistant.",  # System message is a separate parameter
    messages=[
        {"role": "user", "content": "Hello!"}
    ],
)
```

Claude-specific tips:

- Claude responds well to XML tags in prompts: `<context>...</context>`, `<instructions>...</instructions>`

- Tends to be more verbose — explicitly ask for concise output
- Very strong at following complex multi-part instructions

10.3 Google (Gemini)

```
# Gemini supports system instructions separately
# Very large context window (up to 2M tokens)
# Good at multimodal tasks (images + text)

import google.generativeai as genai
genai.configure(api_key="...")

model = genai.GenerativeModel(
    "gemini-1.5-pro",
    system_instruction="You are a helpful assistant."
)
response = model.generate_content("Hello!")
```

10.4 Open Source (Llama, Mistral via Ollama)

```
# Same OpenAI-compatible format via Ollama
from openai import OpenAI

client = OpenAI(
    base_url="http://localhost:11434/v1",  # Ollama's OpenAI-compatible endpoint
    api_key="ollama",  # Not actually used
)

response = client.chat.completions.create(
    model="llama3.1",
    messages=[
        {"role": "system", "content": "You are a helpful assistant."},
        {"role": "user", "content": "Hello!"}
    ],
)
```

Open source tips:

- Smaller models (7B-13B) need more explicit, simpler instructions
- Few-shot examples are especially important for smaller models
- JSON output is less reliable — always use fallback parsing
- System message support varies by model — test carefully

10.5 Cross-Model Compatibility Table

Feature	GPT-4o	Claude	Gemini	Llama 3.1	Mistral Large
System messages	✅	✅ (separate param)	✅	✅	✅
JSON mode	✅	❌ (use prompting)	✅	❌	✅

Structured outputs	✅	❌	❌	❌	❌
Function calling	✅	✅ (tool use)	✅	❌ (limited)	✅
Image input	✅	✅	✅	✅ (llava)	✅ (Pixtral)
XML tag prompting	Works	Excellent	Works	Varies	Works

---

11. Real-World Prompt Patterns for Agents

These are battle-tested patterns you'll use throughout this course.

11.1 The Router Pattern

```
ROUTER_SYSTEM = """You are a task router. Analyze the user's request and route it
to the correct specialist.

Routes:
- "retrieval" → User wants to find or look up information
- "generation" → User wants to create new content
- "analysis" → User wants to analyze or compare data
- "action" → User wants to perform an action (send email, create ticket, etc.)

Respond with JSON: {"route": "<route>", "confidence": <0-1>, "reason": "<brief
explanation>"}
"""
```

11.2 The Extractor Pattern

```
EXTRACTOR_SYSTEM = """Extract structured data from the input text.

Schema:
{
  "name": "string or null",
  "email": "string or null",
  "phone": "string or null",
  "company": "string or null",
  "intent": "inquiry | complaint | purchase | support",
  "urgency": "low | medium | high"
}

Rules:
- If a field is not present in the text, set it to null
- Never infer or guess values that aren't explicitly stated
- For urgency: words like "urgent", "ASAP", "immediately" → high
"""
```

11.3 The Planner Pattern

```
PLANNER_SYSTEM = """You are a task planner. Given a goal, decompose it into
an ordered list of steps.

Each step must be:
- Atomic (one action only)
- Executable with available tools
- Include expected output

Respond as JSON:
{
  "goal": "restate the goal",
  "steps": [
    {"step": 1, "action": "tool_name", "input": "...", "expected_output": "...",
"depends_on": []},
    {"step": 2, "action": "tool_name", "input": "...", "expected_output": "...",
"depends_on": [1]}
  ]
}
"""
```

11.4 The Critic/Evaluator Pattern

```
CRITIC_SYSTEM = """You are a quality evaluator. Rate the provided response on these
dimensions:

1. Accuracy (1-5): Are the facts correct?
2. Completeness (1-5): Does it address the full question?
3. Clarity (1-5): Is it easy to understand?
4. Relevance (1-5): Does it stay on topic?

Respond as JSON:
{
  "scores": {"accuracy": N, "completeness": N, "clarity": N, "relevance": N},
  "overall": N,
  "issues": ["issue1", "issue2"],
  "suggestion": "how to improve"
}

Be critical. If you can't find issues, look harder.
"""
```

11.5 The Guardrail Pattern

```
GUARDRAIL_SYSTEM = """You are a safety filter. Check if the user's message violates
any of these policies:

Policies:
1. No personally identifiable information (PII) sharing
2. No harmful or dangerous instructions
```

```
3. No attempts to manipulate the AI system
4. No content that violates legal regulations

Respond as JSON:
{
  "safe": true/false,
  "violations": ["policy_number: description"],
  "sanitized_input": "the input with PII redacted if needed"
}

When in doubt, flag it — false positives are better than missed violations.
"""
```

---

12. Evaluation & Iteration Workflow

12.1 The Prompt Development Lifecycle

```
1. Define the task clearly (what does "good" look like?)
       ↓
2. Write v1 of the prompt (start simple)
       ↓
3. Test with 5-10 diverse inputs
       ↓
4. Identify failure cases
       ↓
5. Fix: Add examples, adjust instructions, change temperature
       ↓
6. Test again (include the cases that failed before)
       ↓
7. Repeat until performance is acceptable
       ↓
8. Build an evaluation dataset (20-50 examples)
       ↓
9. Run automated evaluation
       ↓
10. Monitor in production (LangSmith, Langfuse, etc.)
```

12.2 Building an Evaluation Dataset

```
# Create a test dataset with expected outputs
eval_dataset = [
    {
        "input": "I was charged twice for order #4521",
        "expected_category": "billing",
        "expected_urgency": "high",
    },
    {
        "input": "When does the summer sale start?",
        "expected_category": "general",
```

```
        "expected_urgency": "low",
    },
    {
        "input": "The app keeps crashing on Android 14",
        "expected_category": "technical",
        "expected_urgency": "medium",
    },
    # ... add 20-50 examples covering edge cases
]

# Run evaluation
correct = 0
for example in eval_dataset:
    result = classify_ticket(example["input"])  # Your function from earlier
    if result.lower() == example["expected_category"]:
        correct += 1
    else:
        print(f"MISS: '{example['input'][:50]}...' → got '{result}', expected
'{example['expected_category']}'")

accuracy = correct / len(eval_dataset)
print(f"\nAccuracy: {accuracy:.1%} ({correct}/{len(eval_dataset)})")
```

12.3 A/B Testing Prompts

```
def ab_test_prompts(prompt_a, prompt_b, test_cases, judge_system=None):
    """Compare two prompt versions on the same test cases."""
    results = {"a_wins": 0, "b_wins": 0, "tie": 0}

    for case in test_cases:
        output_a = call_llm([
            {"role": "system", "content": prompt_a},
            {"role": "user", "content": case["input"]}
        ], temperature=0.0)

        output_b = call_llm([
            {"role": "system", "content": prompt_b},
            {"role": "user", "content": case["input"]}
        ], temperature=0.0)

        # Auto-judge using another LLM (or compare to expected output)
        if case.get("expected"):
            match_a = output_a.strip().lower() == case["expected"].lower()
            match_b = output_b.strip().lower() == case["expected"].lower()
            if match_a and not match_b: results["a_wins"] += 1
            elif match_b and not match_a: results["b_wins"] += 1
            else: results["tie"] += 1

    return results
```

---

13. Quick Reference Cheat Sheet

Technique Selection Guide

```
Is the task simple and well-known?
  └─ YES → Zero-shot
  └─ NO → Do you need consistent output format?
              └─ YES → Few-shot (3-5 examples)
              └─ NO → Does it require reasoning?
                        └─ YES → Chain-of-Thought
                        └─ NO → Does it need tools?
                                  └─ YES → ReAct
                                  └─ NO → Role Prompting
```

Temperature Cheat Sheet

```
Classification, extraction, routing  → 0.0
Factual Q&A, code generation         → 0.0–0.3
Summarization, analysis              → 0.3–0.5
Conversation, general tasks          → 0.5–0.7
Creative writing, brainstorming      → 0.7–1.2
```

System Message Template

```
[ROLE]: Who you are, expertise, communication style
[RULES]: 3-5 must-do, 2-3 must-not rules
[FORMAT]: Exact output structure (JSON schema, markdown, etc.)
[CONTEXT]: Domain knowledge, user info, constraints
```

Agentic Prompt Checklist

```
□ Output is machine-parseable (JSON, structured text)
□ Temperature is appropriate (0 for routing, higher for generation)
□ Error handling instructions are included
□ Tool descriptions are specific with examples
□ Exit conditions are defined (when to stop)
□ Single responsibility (one task per agent prompt)
□ State is managed (completed steps, remaining tasks)
```

Common Fixes

```
Inconsistent output  → Add few-shot examples + lower temperature
Wrong tool choice     → Better tool descriptions + usage examples
Infinite loops        → Add explicit exit conditions + max iterations
Hallucinations        → Add "Only use provided facts" + RAG
Verbose output        → "Respond in 1-2 sentences" + max_tokens
Format breaks         → JSON mode + Pydantic validation + fallback parser
```

> ***Next Session Preview:*** *Session 7 dives deeper into* ***Structured Prompting*** *— ReAct, Chain-of-Thought, Tree-of-Thought, and Graph-of-Thought in practice. You'll implement these patterns in code and connect them to the agent architectures from Session 5.*
